Summary

The poultry meat is considered as a cheap source and rich of animal protein in Egypt compared with red meat, where the proportion of protein in poultry meat is 23% compared with 20% of red meat, 18% of the fish, 2% white meat, 4.3% of the milk.

On the other hand, the lower value of animal proteins per capita in Egypt is considered as an important food problem, and there are two ways to increase it: the first is to expand in importing the animal products, the second is to increase local production and encourage the local producers to continue and enter into production and increase animal and poultry production projects. Here, the fundamental problem of the study rises which is being unclear about the constant level of the quantity and value of the production of the broiler chickens in recent time as a result of the transmission and spread of avian flu in Egypt.
